

On the Transitive Amplification of Sexiness in a Closed Systems

Dr Jamie Gabriel
University of Breastenburg, Bangheim

Abstract

We present a formal model demonstrating that within a sufficiently constrained system, each instance of sexiness exhibited by an agent (hereafter Sally) necessarily induces an increase in the perceived sexiness of all other actions performed by said agent. Using the natural exponential function as a generative mechanism, we prove that sexiness in this system is not additive but multiplicative, exhibiting properties analogous to continuous growth governed by Euler's number e

Introduction

Previous work in aesthetic contagion (cf. Vibes et al., n.d.) has noted that certain individuals exhibit a property whereby isolated actions cannot be evaluated independently. Sally represents a canonical example of such a system.

Empirically, observers report that once Sally performs one sexy thing, all subsequent things—regardless of intrinsic content—are reclassified as sexy. This paper seeks to provide a rigorous mathematical explanation for this phenomenon.

2. Definitions

Let:

$$S(t)$$

denote the global sexiness level of Sally at time t .

$$a_i$$

denote the i -th action performed by Sally.

$$s(a_i)$$

denote the local sexiness contribution of action a_i .

3. The Eulerian Sexiness Model

We propose that Sally's sexiness evolves according to the differential equation:

$$dS/dt = kS$$

where $k > 0$ is the Sally constant, empirically large and poorly understood.

Solving yields:

$$S(t) = S_0 e^{kt}$$

4. The Transitivity Theorem

Theorem 1 (Sexiness Transitivity): If Sally performs at least one sexy action, then all subsequent actions inherit sexiness.

Proof:

Consider an action a_j such that $s(a_j) > 0$. This establishes $S(t) > 0$.

Since $S(t)$ follows $S(t) = S_0 e^{kt}$, we note that $S(t)$ is strictly increasing, never returns to baseline, and multiplies all future

evaluations.

$$\text{Perceived} \backslash \text{sexiness}(a_{\{j+n\}}) \\ = s(a_{\{j+n\}}) \cdot S(t)$$

5. Corollary: Irrelevance of Action Content

Once $S(t)$ exceeds a critical threshold, the semantic content of actions becomes irrelevant.

Documented observations include:

- Sally tying her shoes (classified as sexy).
- Sally reading instructions (also sexy).
- Sally doing nothing (paradoxically extremely sexy).

6. Methods

We observed Sally over multiple days, recording each action and using observer-continuous metrics to quantify sexiness. All measurements were normalized and converted into exponential growth parameters. This section serves as a formal placeholder for methodology, demonstrating the plausible rigor of our approach.

7. Limitations

While our model captures the multiplicative and exponential nature of sexiness, it is limited to a single-agent system (Sally). External damping factors, observer bias, and cross-agent generalizability remain unexplored and warrant further investigation.

8. Discussion

The use of Euler's function is not incidental. As with population growth, sexiness in this model represents continuous compounding of perception. Each sexy act does not merely add to Sally's sexiness, but rescales the entire system.

Attempts to undo the effect fail because exponential systems lack a natural inverse without external damping, which has not been observed.

9. Conclusion

Sally's sexiness operates as an exponential field rather than a property of individual actions. Each sexy act makes all others sexy not by exaggeration, but by necessity.

Further research will examine whether this phenomenon generalises beyond Sally, though evidence suggests she is a special case.
